**Priorix-Tetra™**  
Measles, mumps, rubella and varicella vaccine (live, attenuated)

**QUALITATIVE AND QUANTITATIVE COMPOSITION**

After reconstitution, 1 dose (0.5 ml) contains:

- Live attenuated measles virus\(^1\) (Schwarz strain) not less than \(10^{3.0}\) CCID\(_{50}\)^\(^3\)
- Live attenuated mumps virus\(^1\) (RIT 4385 strain, derived from Jeryl Lynn strain) not less than \(10^{4.4}\) CCID\(_{50}\)^\(^3\)
- Live attenuated rubella virus\(^2\) (Wistar RA 27/3 strain) not less than \(10^{3.0}\) CCID\(_{50}\)^\(^3\)
- Live attenuated varicella virus\(^2\) (OKA strain) not less than \(10^{3.3}\) PFU\(^4\)

\(^1\) produced in chick embryo cells  
\(^2\) produced in human diploid (MRC-5) cells  
\(^3\) Cell Culture Infective Dose 50%  
\(^4\) Plaque forming units

The powder is white to slightly pink.  
The solvent is clear and colourless.

**PHARMACEUTICAL FORM**

Powder and solvent for solution for injection.

**CLINICAL PARTICULARS**

**Indications**

*Priorix-Tetra™* is indicated for active immunisation in subjects from the age of 12 months onwards up to 12 years of age inclusive against measles, mumps, rubella and varicella. (see also Warnings and Precautions, Pharmacodynamics).

**Dosage and Administration**

**Posology**

Primary immunisation consists of one dose of vaccine.  
A second dose of measles-containing vaccine should be administered according to the Singapore’s national immunization program.

It is preferable to respect an interval of at least 6 weeks between doses. In no circumstances should this interval be less than 4 weeks.

**Method of administration**

For subcutaneous injection, preferably into the outer aspect of upper arm.
For information on instructions for preparation or reconstitution please refer to the “Instructions for Use/Handling” section.

**Contraindications**

*Priorix-Tetra*™ is contraindicated in subjects with known hypersensitivity to neomycin or to any other component of the vaccine (for egg allergy, see Warnings and Precautions). A history of contact dermatitis to neomycin is not a contraindication.

*Priorix-Tetra*™ is contraindicated in subjects having shown signs of hypersensitivity after previous administration of measles, mumps, rubella and/or varicella vaccines.

*Priorix-Tetra*™ is contra-indicated in pregnant women. Pregnancy should be avoided for one month after vaccination (see Pregnancy and Lactation).

Priorix-Tetra”™ is contraindicated in subjects with severe humoral or cellular (primary or acquired) immunodeficiency, e.g. severe combined immunodeficiency, agammaglobulinemia and AIDS or symptomatic HIV infection or an age-specific CD4+ T-lymphocyte percentage in children below 12 months: CD4+ <25%; children between 12-35 months: CD4+ < 20%; children between 36-59 months: CD4+ < 15% (see also Warnings and Precautions).

**Warnings and Precautions**

As with all injectable vaccines, appropriate medical treatment and supervision should always be readily available in case of a rare anaphylactic event following the administration of the vaccine.

As with other vaccines, the administration of Priorix-Tetra”™ should be postponed in subjects suffering from acute severe febrile illness. However, the presence of a minor infection, such as a cold, should not result in the deferral of vaccination.

Syncope (fainting) can occur following, or even before, any vaccination as a psychogenic response to the needle injection. It is important that procedures are in place to avoid injury from faints.

Alcohol and other disinfecting agents must be allowed to evaporate from the skin before injection of the vaccine since they can inactivate the attenuated viruses in the vaccine.

Limited protection against measles or varicella may be obtained by vaccination up to 72 hours after exposure to natural disease.

Infants in their first year of life may not respond sufficiently to the measles component of the vaccine, due to the possible persistence of maternal measles antibodies. Additional doses of a measles containing vaccine should be given according to official recommendations.
There is an increased risk of fever and febrile convulsions 5 to 12 days after the first dose of Priorix-Tetra™ as compared with 2 separate injections of MMR and varicella vaccines (see Adverse Reactions and Pharmacodynamics). There was no indication of an increased risk after the second dose.

Fever rates are usually high after the first dose of measles-containing vaccines.

Vaccination of subjects with a history of febrile convulsions or a family history of convulsions should be considered with caution. Alternative immunisation of these subjects with separate MMR and varicella vaccines should be considered for the first dose (see Posology). In any case vaccinees should be monitored for fever during the risk period.

The measles and mumps components of the vaccine are produced in chick embryo cell culture and may therefore contain traces of egg protein. Persons with a history of anaphylactic, anaphylactoid, or other immediate reactions (e.g. generalised urticaria, swelling of the mouth and throat, difficulty breathing, hypotension, or shock) subsequent to egg ingestion may be at an enhanced risk of immediate-type hypersensitivity reactions after vaccination, although these types of reactions have been shown to be very rare. Individuals who have experienced anaphylaxis after egg ingestion should be vaccinated with extreme caution, with adequate treatment for anaphylaxis on hand should such a reaction occur.

Transmission of measles, mumps and rubella viruses from vaccinees to susceptible contacts has never been documented, although pharyngeal excretion of the rubella virus is known to occur about 7 to 28 days after vaccination with peak excretion around the 11th day. Post-marketing experience suggests that transmission of varicella vaccine virus may occur very rarely between healthy vaccinees who develop a varicella-like rash and susceptible contacts.

Transmission of the Oka vaccine virus has been shown to occur at a very low rate in seronegative contacts of vaccinees with rash. Transmission of the Oka vaccine from a vaccinee who does not develop a rash to seronegative contacts cannot be excluded.

Priorix-Tetra™ must not be administered intravascularly or intradermally.

As with any vaccine, a protective immune response may not be elicited in all vaccinees. As for other varicella vaccines, cases of varicella disease have been shown to occur in persons who have previously received Priorix-Tetra™. These breakthrough cases are usually mild, with a fewer number of lesions and less fever as compared to cases in unvaccinated individuals.

Cases of worsening of thrombocytopenia and recurrence of thrombocytopenia in subjects who suffered thrombocytopenia after the first dose have been reported following vaccination with live measles, mumps and rubella vaccines. In such cases, the risk-benefit of immunising with Priorix-Tetra™ should be carefully evaluated.

Vaccination may be considered in patients with selected immune deficiencies where the
benefits outweigh the risks (e.g. asymptomatic HIV subjects, IgG subclass deficiencies, congenital neutropenia, chronic granulomatous disease, and complement deficiency diseases).

Immunocompromised subjects who have no contraindication for this vaccination (see Contraindications) may not respond as well as immunocompetent subjects, therefore some of these subjects may acquire measles, mumps, rubella or varicella despite appropriate vaccine administration. Immunocompromised subjects should be monitored carefully for signs of measles, mumps, rubella and varicella.

Very few reports exist on disseminated varicella with internal organ involvement following vaccination with Oka varicella vaccine strain mainly in immunocompromised subjects.

**Interactions**

*Priorix-Tetra™* can be given simultaneously (but at separate injection sites) with any of the following monovalent or combination vaccines [including hexavalent vaccines (DTPa-HBV-IPV/Hib)]: diphtheria-tetanus-acellular pertussis vaccine (DTPa), *Haemophilus influenzae* type b vaccine (Hib), inactivated polio vaccine (IPV), hepatitis B vaccine (HBV).

If tuberculin testing has to be done it should be carried out before or simultaneously with vaccination since it has been reported that combined measles, mumps and rubella vaccines may cause a temporary depression of tuberculin skin sensitivity. As this anergy may last up to a maximum of 6 weeks, tuberculin testing should not be performed within that period after vaccination to avoid false negative results.

In subjects who have received human gammaglobulins or a blood transfusion, vaccination should be delayed for at least three months because of the likelihood of vaccine failure due to passively acquired antibodies.

Salicylates should be avoided for 6 weeks after each vaccination as Reye’s Syndrome has been reported following the use of salicylates during natural varicella infection.

**Pregnancy and Lactation**

**Pregnancy**
Pregnant women must not be vaccinated with *Priorix-Tetra™*. Pregnancy should be avoided for one month after vaccination. Women who intend to become pregnant should be advised to delay pregnancy.

Adequate human data on the use of *Priorix-Tetra™* during pregnancy are not available and animal studies on reproductive toxicity have not been conducted.

**Lactation**
Adequate human data on the use of *Priorix-Tetra™* during lactation are not available.

**Effects on Ability to Drive and Use Machines**

Not relevant.
Adverse Reactions

The safety profile presented below is based on data from more than 6,700 doses administered to children from 9 to 27 months of age. Events were recorded for up to 42 days after vaccination.

Frequencies are reported as:
Very common (≥1/10)/ Common (≥1/100 to <1/10)/ Uncommon (≥1/1,000 to <1/100)/ Rare (≥1/10,000 to <1/1,000)/ Very rare (<1/10,000)

Immune system disorders
Rare
allergic reactions (including anaphylactic and anaphylactoid reactions)

Nervous system disorders
Rare
encephalitis, cerebrovascular accident, cerebellitis, cerebellitis like symptoms, (including transient gait disturbance and transient ataxia), Guillain-Barré syndrome, transverse myelitis, peripheral neuritis

Vascular disorders
Rare
vasculitis (including Henoch Schönlein purpura and Kawasaki syndrome)

Skin and subcutaneous tissue disorders
Rare
erythema multiforme, varicella like rash

Musculoskeletal and connective tissue disorders
Rare
arthralgia, arthritis

Overdose
Insufficient data are available.

**PHARMACOLOGICAL PROPERTIES**

**Pharmacodynamics**

**Efficacy and effectiveness**

Clinical trials showed that the vast majority varicella vaccinees exposed to wild-type virus were either completely protected or developed a milder form of chickenpox (breakthrough varicella).

The efficacy of GlaxoSmithKline’s Oka/RIT varicella vaccines in preventing confirmed varicella disease (by PCR or exposure to varicella case) was evaluated in a large active controlled clinical trial in which children aged 12-22 months received two doses of Priorix-Tetra (N = 2279) or one dose of monovalent Oka/RIT vaccine (N = 2263). The observed vaccine efficacy against confirmed varicella of any severity and against moderate or severe confirmed varicella were respectively 94.9% (97.5% CI: 92.4-96.6%) and 99.5% (97.5% CI: 97.5-99.9%) after 2 doses of Priorix-Tetra and 65.4 % (97.5% CI: 57.2-72.1%) and 90.7% (97.5% CI: 85.9-93.9%) after one dose of monovalent Oka/RIT vaccine (mean follow-up period 35 months).

Effectiveness data suggest a higher level of protection and a decrease in breakthrough varicella following two doses of varicella-containing vaccine than following one dose. In an outbreak situation the effectiveness of two doses of Priorix-Tetra was 91% (95% CI: 65-98%) against any disease and 94% (95% CI: 54-99%) against moderate disease.

Immune response: Seroconversion rates after two doses of Priorix-Tetra described as follows in approximately 2,000 previously unvaccinated children from 11 to 23 months of age are summarized in the table below:
<table>

</tbody>
</table>

ELISA: Enzyme Linked Immuno Sorbent Assay
IFA: Immunofluorescence Assay

In a large efficacy trial two years after vaccination with two doses of Priorix-Tetra; seropositivity rates for anti-varicella antibodies were 99.4% (ELISA) and 99.2% (IFA) and respectively 99.1%, 90.5% and 100% for anti-measles, mumps and rubella antibodies (ELISA).

Post-Marketing Observational Safety Surveillance Study

The risk of febrile convulsions following the first dose vaccination of children aged 9 to 30 months with Priorix-Tetra™ compared with a matched cohort who received MMR or simultaneous, but separate MMR and varicella vaccination was assessed in a retrospective database analysis.

The study included 82,656 children immunized with MMRV, 149,259 with MMR and 39,203 with separate MMR and varicella vaccines.

The attributable risk of febrile convulsions on cohorts matched for confounding factors in the main risk period of 5 to 12 days following first dose of Priorix-Tetra™ was 3.64/10,000 (95% CI: -6.11; 8.30).

Pharmacokinetics

Evaluation of pharmacokinetic properties is not required for vaccines.

Clinical Studies

See section “Pharmacodynamics”

Preclinical Safety Data

A repeated dose toxicity study in animals did not reveal any local or systemic toxicity of the vaccine.
PHARMACEUTICAL PARTICULARS

List of Excipients

Excipients of the vaccine are: amino acids, lactose, mannitol, sorbitol.

Solvent is water for injections.

Neomycin sulphate is present as a residual from the manufacturing process.

Incompatibilities

In the absence of compatibility studies, this medicinal product must not be mixed with other medicinal products.

Shelf Life

The expiry date of the vaccine is indicated on the label and packaging.

After reconstitution: immediate use is recommended. However the stability at +2°C to +8°C has been demonstrated for 8 hours after reconstitution.

Special Precautions for Storage

Store at 2°C – 8°C (in a refrigerator)
Do not freeze.
Store in the original packaging in order to protect from light.

Nature and Contents of Container

Powder in a vial (Type I glass) with a stopper.
0.5 ml of solvent in an ampoule (Type I glass)
or
0.5 ml of solvent in a pre-filled syringe (Type I glass) with rubber stopper, with or without needles

Instructions for Use/Handling

The reconstituted vaccine should be inspected visually for any foreign particulate matter and/or abnormal physical appearance. In the event of either being observed, the vaccine should be discarded.

The vaccine is reconstituted by adding the entire contents of the supplied container of diluent to the vial containing the powder. After the addition of the diluent to the powder, the mixture should be well shaken until the powder is completely dissolved.

The colour of the reconstituted vaccine may vary from clear peach to fuchsia pink due to minor variations of its pH. This is normal and does not impair the performance of the vaccine. In the event of other variation being observed, discard the vaccine.

Any unused product or waste material should be disposed of in accordance with local requirements.
Not all presentations are available in every country.
